## 5    **ABSTRACT OF THE DISCLOSURE**

[1037] A sequentially performed implementation of a compound compare-and-swap (nCAs) operation has been developed. In one implementation, a double compare-and-swap (DCAS) operation does not result in a fault, interrupt, or trap in the situation where memory address A2 is invalid and the contents of memory address A1 are  
10    unequal to C1. In some realizations, memory locations addressed by a sequentially performed nCAs or DCAS instruction are reserved (e.g., locked) in a predefined order in accordance with a fixed total order of memory locations. In this way, deadlock between concurrently executed instances of sequentially performed nCAs instructions can be avoided. Other realizations defer responsibility for deadlock  
15    avoidance to the programmer.
